Abstract

The Bellvue Coal Mine, located on the West Coast north of Greymouth, ceased production in 1970 but continues to discharge acid mine drainage (AMD) at an average flow rate of 0.93 L/s into nearby Cannel Creek. The chemistry of the AMD has low pH (2.28-3.01) and elevated concentrations of dissolved metals (69 mg/L Fe, 39 mg/L Al, 0.76 mg/L Mn, 0.32 mg/L Zn, 0.15 mg/L Ni). The water quality in Cannel Creek changes from a near-neutral pH stream with low metal concentrations upstream of the confluence to a stream with a pH of between 2.8 and 4.3 with elevated concentrations of dissolved metals. Approximately 550 m downstream, AMD from the abandoned James Mine flows into Cannel Creek, further lowering the pH and increasing the metal concentrations. This AMD has an average flow rate of 0.14 L/s and a pH of 2.41-2.80 and metal concentrations of 148 mg/L Fe, 200 mg/L Al, 6.5 mg/L Mn, 1.21 mg/L Zn and 0.56 mg/L Ni. This study evaluated the current relative impact of these two AMD sources on Cannel Creek, and modelled theoretical pH and metal concentrations in Cannel Creek once a planned passive treatment system is installed at the Bellvue Mine.

The creek and AMD flow rates show an asynchronous pattern in response to precipitation events. Cannel Creek flow peaks 24 hours after maximum precipitation and the AMD flow rates (both) peak an additional 24 hours later. The acid load to Cannel Creek is therefore greatest at the tail end of storm events when the AMD flow rates are still elevated but Cannel Creek is returning to base level. Overall, Bellvue contributes between 60% and 90% of the hydrogen ion acidity to the creek, with relatively greater contributions at low flow. Once the treatment system is installed, the remaining impact to Cannel Creek will mostly occur downstream of the James Mine during middle- and post-storm conditions. Future plans should be made to address the James Mine AMD.

Keywords: acid mine drainage, modelling, passive treatment, mussel shells, Bellvue Mine.

Introduction

Acid mine drainage (AMD) is a well known liability at both coal and metal mines throughout the world (INAP, 2009). It is a legacy of many abandoned mines in many countries, and also dominates water management efforts at active mine sites (Hickman et al., 2012; Jarvis et al., 2012; Williams and Bierbach, 2012). Many countries have abandoned mines programmes for assessment and remediation of abandoned mine sites, however, no such programme exists for New Zealand. Most AMD in New Zealand occurs on the West Coast of the South Island, and it is estimated that 125 km of waterways are affected by AMD on the West Coast alone (James, 2003).

As part of a Ministry of Business, Innovation and Employment research grant focused on understanding and managing environmental impacts of on-shore mining in New Zealand, the Centre for Minerals Environmental Research (CMER) is planning remediation of AMD at the abandoned underground Bellvue Coal Mine, located on the West Coast approximately 15 km northeast of Greymouth. This project serves as an example of methodologies that could be potentially applied to abandoned AMD sites in New Zealand.

Previous work in the area found that the Bellvue AMD, and several additional AMD sources downstream, discharge into the nearby Cannel Creek, resulting in significant impact (Trumm and Cavanagh, 2006). Approximately 62% of the impact to the creek was found to be caused by the Bellvue AMD, 33% of the impact from the abandoned James Mine AMD (located 550 m downstream of the Bellvue Mine) and the remaining 5% from the abandoned Jubilee Mine AMD (located 10 m downstream of the Bellvue Mine) (Fig. 1). It was concluded that remediation at the Bellvue Mine would help to restore much of Cannel Creek.

Small-scale remediation trials were completed at the Bellvue site to identify a suitable remediation technique for the AMD (West, 2014); based on this work, an up-flow mussel shell reactor has been selected as the remediation solution. Prior to installation of the system, a geochemical conceptual model was developed to understand the current conditions in Cannel Creek from the two major AMD sources, the Bellvue Mine AMD and the James Mine AMD, to predict how treatment of the Bellvue AMD will change the conditions downstream in Cannel Creek and to ensure treatment will achieve suitable water quality targets. The conceptual model is presented in this work.

Methods

Flow rates were measured in Cannel Creek and James Creek (a tributary to Cannel Creek 150 m downstream of the James Mine; Fig. 1) using a SonTek FlowTracker with a 2D side-looking ADV water velocity sensor. Flow rates were measured in the two AMD sites using a bucket and stopwatch method. An Intech WT-HR 1m data logger was installed in the pool in the Bellvue Mine adit and used to take automatic readings of water height every 30 minutes. The logger operated from 11 July 2013 to 12 June 2015. Precipitation data were obtained from the NIWA climatic station Greymouth Aero for the time period 1 September 2005 to 17 May 2016.

Field measurements were collected from the two AMD sources, Cannel Creek and James Creek, using a portable YSI 556 multi-probe system. Samples were collected for laboratory analyses and analysed for major chemical parameters commonly used for AMD sites, including pH, acidity, alkalinity, sulphate and metals using APHA methods (APHA, 2005).

Geochemical modelling was completed on mixed solutions using the geochemical modelling programme PHREEQC (version 2) (Appelo and Parkhurst, 1999). In all cases, the model was first run to determine the degree of saturation (saturation index) of Al-bearing minerals and Fe-bearing minerals. If Gibbsite or Schwertmannite were found to be above saturation, the model was then run again, specifying that these minerals would be at equilibrium with the final solution. In these cases, the resulting pH and metal concentrations were always lower. It is likely that true values lie somewhere between these two extremes for each case.

Three important assumptions have been made in this work. Firstly, water level measurements from the datalogger in the Bellvue Mine pool from 11 July 2013 to 12 June 2015 are representative of typical water levels in the pool and correlation of datalogger data with AMD flow rates is adequate to determine flow rates during this period. Secondly, precipitation at the Greymouth Airport is similar to the precipitation in the Bellvue Mine area and correlation of total precipitation over the previous 24 hours is adequate to determine the flow rates from the precipitation data. Thirdly, correlation of James Mine AMD and the Bellvue Mine AMD flow rates is adequate to determine flow rates in the James Mine AMD and the delay time between

precipitation events and increased flow rates in the James Mine AMD is similar to the Bellvue Mine AMD.

Figure 1. Topographic map of area. Results

Flow rates

Water in the Bellvue mine pool ranged from a depth of 133 mm to 1183 mm with an average of 565 mm. Correlation of this data with measured flow rates show flow rates between 0.041 L/s and 30.3 L/s with an average of 0.93 L/s and median of 0.54 L/s. The data is characterised by low base level flows with short duration spikes where flow rates first increase rapidly and then decline back to base level at a somewhat slower rate (Fig. 2a). An analysis of the flow rates shows that 92% of the flow rates are less than 2 L/s, with 47% below 0.5 L/s. Less than 1% of the flow rates are greater than 5 L/s (Table 1).

Flow rates from the James Mine AMD are much less than the flow rates from the Bellvue Mine AMD and there is linear correlation between the two sites. Over the period of data collection from the datalogger in the Bellvue Mine pool, flow rates from the James Mine AMD range from 0 L/s to 6.0 L/s with an average of 0.14 L/s and a median of 0.06 L/s. Flow rates were less than 0.40 L/s 95% of the time and less than 0.06 L/s 50% of the time. Less than 1% of the flow rates are greater than 0.9 L/s.

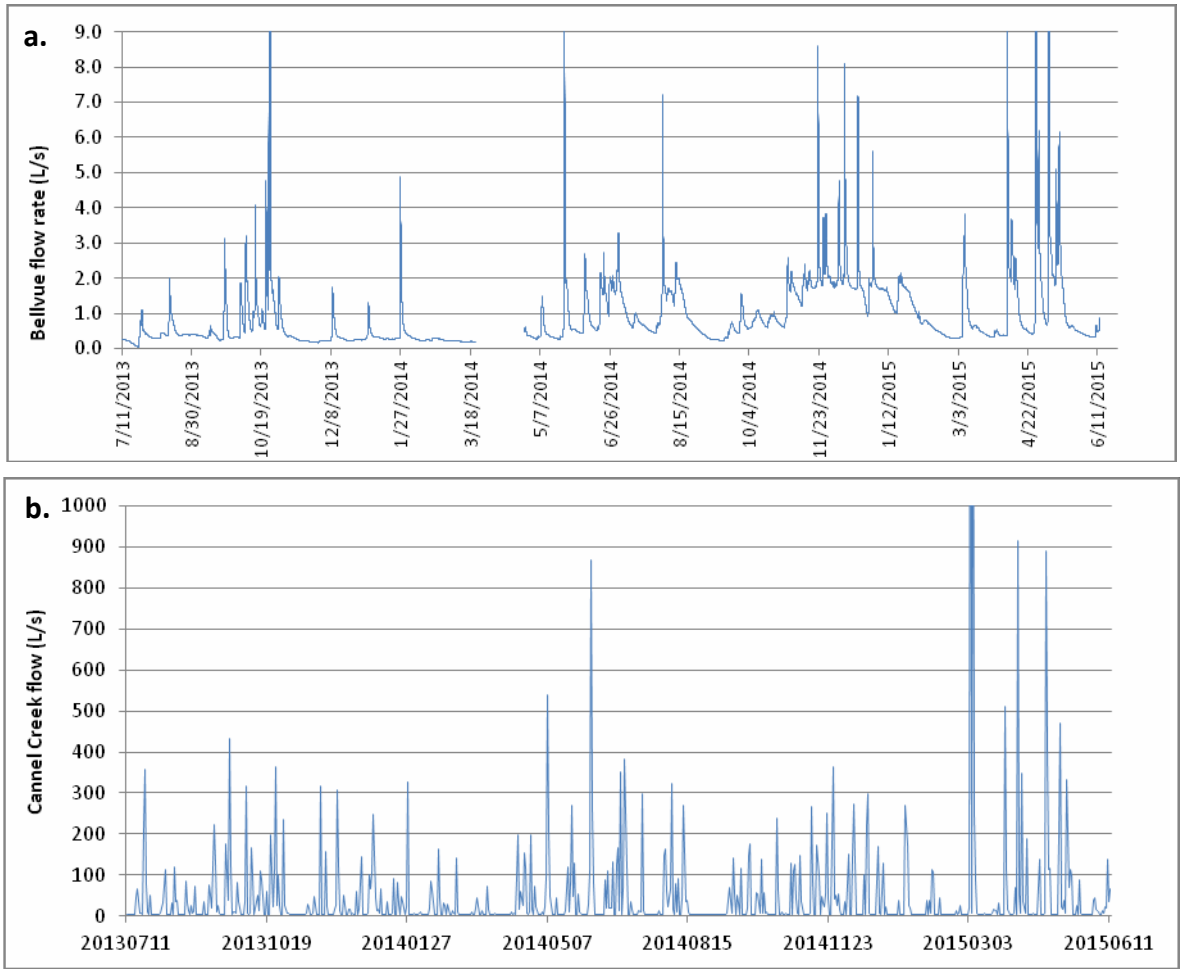

Figure 2. a. Bellvue Mine flow rate; **b.** Cannel Creek flow rate.

Using a correlation between measured flow rates and total precipitation over the previous 24 hours, flow rates for Cannel Creek range from a baseline flow of 2.7 L/s to a maximum of 3,831 L/s with an average of 50 L/s (Fig. 2b). Flow rates are characterised by a baseline level with short duration and high flow rates during storm events. Eighty percent of the flow rates are less than 50 L/s, 17% range from 50 to 300 L/s, and 3% are greater than 300 L/s (Table 1).

Table 1. Frequency of flow rates in Bellvue AMD and in Cannel Creek upstream of Bellvue AMD.

Bellvue AMD			Cannel Creek	
Flow rate (L/s)	Frequency		Flow rate (L/s)	Frequency
< 0.25	13%		< 5	54.7%
0.25 - 0.50	34%		5 - 10	7.0%
0.50 - 0.75	16%		10 - 15	3.9%
0.75 - 1.00	7%		15 - 20	3.4%
1.00 - 1.25	4%		20 - 25	2.5%
1.25 - 1.50	3%		25 - 30	2.2%
1.50 - 1.75	7%		30 - 35	1.7%
1.75 - 2.00	6%		35 - 40	1.9%
2.00 - 2.25	3%		40 - 45	1.0%
2.25 - 2.50	1.2%		45 - 50	1.5%
2.50 - 3.00	1.4%		50-100	7.9%
> 3.00	2.8%		> 100	12.1%

James Creek shows flow rates 20% to 50% of that measured in Cannel Creek. It is assumed that the response of flow in this creek to precipitation events is similar to that of Cannel Creek.

The flow rate in Cannel Creek, upstream of Bellvue Mine, does not show a significant correlation to the flow rate of the Bellvue Mine AMD, suggesting that high flow rates during storm events are not synchronised between the two. The data show that during storm events, the flow rate in Cannel Creek peaks approximately 24 hours after maximum precipitation and the flow rate in the AMD peaks an additional 24 hours after maximum precipitation. While the AMD flow rate peaks, the flow rate in Cannel Creek has already begun to decline, and can reach baseline levels while the AMD flow rate is still elevated (Fig. 3). The relationship of flow rates in Cannel Creek and James Creek to the James Mine AMD show the same pattern.

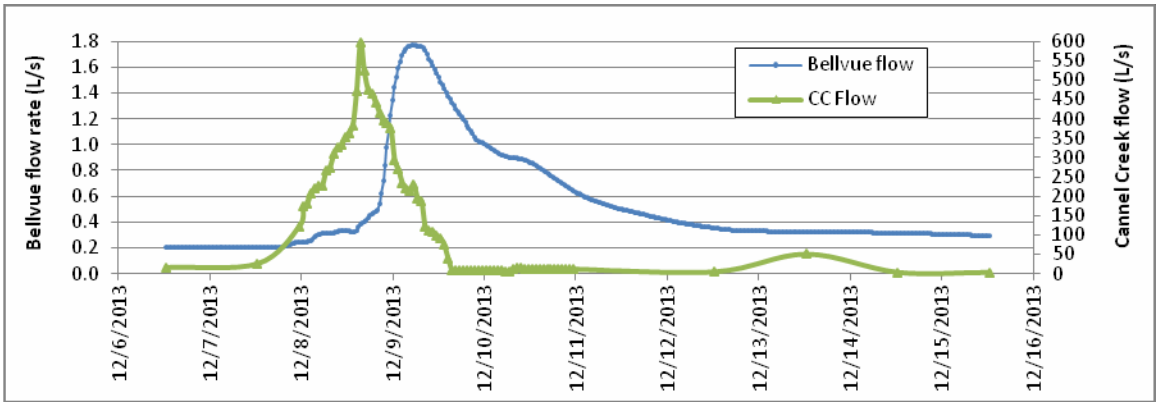

Figure 3. Example of asynchronous flow pattern between the Bellvue AMD and Cannel Creek.

Current chemistry

The pH in the Bellvue Mine AMD ranges from 2.28 to 3.01, and average dissolved metal concentrations are: Fe 69 mg/L, Al 39 mg/L, Mn 0.76 mg/L, Zn 0.32 mg/L and Ni 0.15 mg/L (Fig. 4a). The calculated acidity averages 543 mg/L. Water quality does not dilute significantly with increase in flow rates. The relatively stable water chemistry across flow rates results in an increase in acid load leaving the mine with increase in flow rates (Fig. 4b). Using the full range of flow rates calculated from the datalogger data, the acid load ranges from 6.9 to 918 kg/d (an average of 35 kg/d).

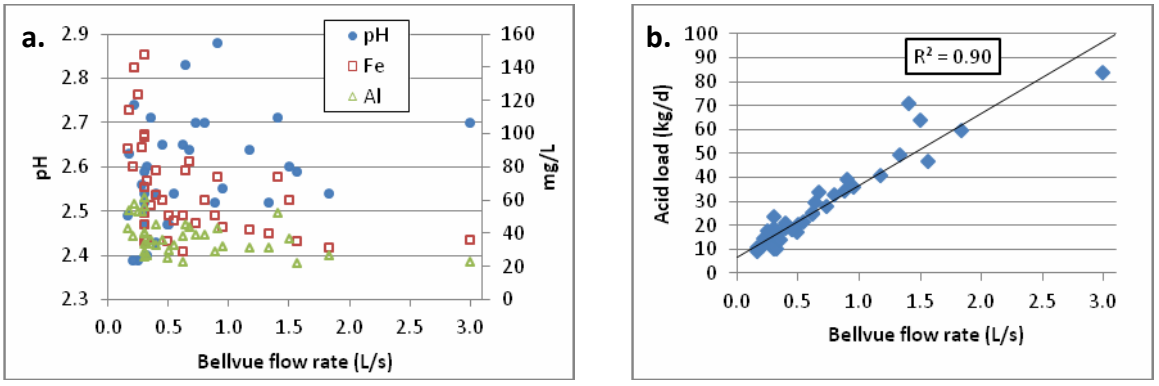

Figure 4. Bellvue Mine AMD **a.** Chemistry, **b.** acid load.

The pH in the James Mine AMD ranges from 2.41 to 2.80, and average dissolved metal concentrations are: Fe 148 mg/L, Al 200 mg/L, Mn 6.5 mg/L, Zn 1.21 mg/L and Ni 0.56 mg/L. The calculated acidity averages 1647 mg/L. Similar to the Bellvue Mine AMD, water quality does not dilute significantly with increase in flow rates, and the relatively stable water chemistry across flow rates results in an increase in acid load leaving the mine with increase

in flow rates. Using the full range of flow rates calculated from the datalogger data, the acid load ranges from 0 to 899 kg/d (an average of 21 kg/d).

A comparison of the acid loads to Cannel Creek from the two AMD sources across the range of flow rates shows that the Bellvue AMD contributes relatively more acidity at low flow than at high flow (Fig. 5). At a Bellvue flow rate of 0.10 L/s, the Bellvue AMD contributes 90% of the sum of the two acid loads. At a flow rate of 1.2 L/s, Bellvue contributes 60% and at a flow rate of 2 L/s, the contribution from Bellvue is only 58%. Since Bellvue Mine AMD flow rates are less than 1.4 L/s 77% of the time, then the relative contribution to Cannel Creek from Bellvue is mostly 60 to 90% and from the James Mine AMD is mostly 10 to 40%.

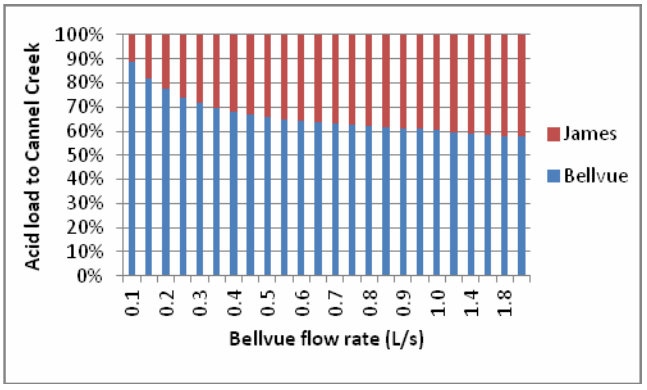

Figure 5. Relative acid loads to Cannel Creek from the Bellvue and James Mine AMDs.

The pH in Cannel Creek upstream of the Bellvue Mine AMD ranges from 4.60 to 7.28, and average Fe concentrations are 0.29 mg/L and Al concentrations are 0.14 mg/L. Alkalinity ranges from 3.0 to 25 mg/L. Water quality dilutes slightly with increase in flow rate.

Downstream of the Bellvue Mine AMD, the pH in Cannel Creek ranges from 2.76 to 4.30, and average dissolved Fe concentrations are 6.49 mg/L and Al concentrations are 5.91 mg/L. Alkalinity is < 1 mg/L and the calculated acidity averages 83.4 mg/L. Water quality dilutes with increase in flow rate, however there is some scatter in the data due to the asynchronous flow rates between Cannel Creek and the AMD during storm events resulting in variable acid load reporting to the Cannel Creek. Downstream of the James Mine AMD, the water chemistry in Cannel Creek is further degraded, resulting in a pH between 3.11 and 3.75, Fe concentrations of 3.3 mg/L, Al concentrations of 4.3 mg/L and acidity of 42 mg/L.

The water chemistry data for James Creek show a pH of 7.06 to 7.14, Fe concentrations of 0.27 mg/L, Al concentrations of 0.131 mg/L and alkalinity of 25 mg/L. Downstream of the confluence with James Creek, the water chemistry in Cannel Creek improves to a pH between 3.25 and 4.32, Fe concentrations of 2.1 mg/L, Al concentrations of 3.3 mg/L and acidity of 26.4 mg/L.

Geochemical modelling

Bellvue Mine AMD and Cannel Creek

The asynchronous pattern of the flow regimes in Cannel Creek and the AMD during precipitation events has been analysed to determine relative flow rates to be used for geochemical modelling of current stream chemistry and predicted chemistry post treatment of the Bellvue Mine AMD. The data show that for approximately 49% of the time, there has been no precipitation in the previous 24 hours and both Cannel Creek and the AMD are at

base flow conditions. The modelled flow rates for this category are 2.7 L/s for Cannel Creek and 0.5 L/s for the AMD. For the remaining 51% of the time, Cannel Creek and the AMD are influenced by precipitation events. These precipitation events have been placed into five categories as follows:

(a) Start of Precipitation: Cannel Creek is at moderate flow; AMD is at base flow
(b) Middle Precipitation-1: Cannel Creek is at high flow; AMD is at moderate flow
(c) Middle Precipitation-2: Cannel Creek is at high flow; AMD is at high flow
(d) End Precipitation-1: Cannel Creek is at moderate flow; AMD is at moderate flow
(e) End Precipitation-2: Cannel Creek is at base flow; AMD is at moderate flow

The results of the modelling predict the current pH in Cannel Creek downstream of the Bellvue AMD ranges between 2.95 and 4.76, depending on relative flow rates of the stream and the AMD and depending on if Fe and Al minerals are at equilibrium with the water (Table 2).

Table 2. Modelling results for Cannel Creek below Bellvue AMD under current conditions.

Frequency	Duration in three-day storm	Condition	Cannel Creek flow (L/s)		Bellvue AMD flow (L/s)		Cannel Creek (just above and just below Bellvue Mine)							
							pH		Fe		Al		Alkalinity	
							Upstream	Downstream	Upstream	Downstream	Upstream	Downstream	Upstream	Downstream
49%		no precipitation	base flow	2.7	base flow	0.5	6.09	3.25	0.30	12.7	0.09	6.64	12.76	0
								3.06		2.16		6.64		
18%	*25 hours*	start precipitation	moderate flow	25	base flow	0.75	5.29	4.31	0.25	2.58	0.14	1.37	9.12	0
								4.11		0.067		1.37		
11%	*16 hours*	middle precipitation-1	high flow	100	moderate flow	1.5	5.12	4.76	0.33	0.81	0.23	0.56	3.94	0
								4.45		0.04		0.27		
9%	*13 hours*	middle precipitation-2	high flow	100	high flow	5	5.12	3.96	0.33	1.71	0.23	1.42	3.94	0
								3.86		0.11		1.42		
10%	*14 hours*	end precipitation-1	moderate flow	25	moderate flow	1.5	5.29	3.92	0.25	3.12	0.14	2.11	9.12	0
								3.77		0.15		2.11		
3%	*4 hours*	end precipitation-2	base flow	3.5	moderate flow	1.5	6.09	3.09	0.30	14.6	0.09	9.97	12.76	0
								2.95		4.86		9.97		

The lowest pH and highest metal concentrations occur at the very end of precipitation events, when Cannel Creek is near base flow conditions and the AMD is still at moderate flow (“e” category). The next lowest pH occurs during low flow conditions between precipitation events (“No Precipitation” category). The next lowest pH condition also occurs near the end of precipitation events when moderate flow in Cannel Creek is influenced by moderate flow from the AMD (“d” category). The other three modelled conditions, during the start and middle of precipitation events when the flow rate of Cannel Creek is substantially greater than that of the AMD, show relatively high pH in the stream and dilution of metal concentrations reporting from the AMD.

Modelling was completed again for all six flow categories assuming up to 1 L/s of the Bellvue AMD was treated and then discharged to the stream (Table 3). For the categories where the AMD flow rate was greater than 1 L/s (all flow conditions with the exception of “No Precipitation” and “a” category), the modelling included mixing of the untreated AMD with the treated AMD prior to mixing with Cannel Creek. The results show that overall, 88% to 91% of the time the pH in Cannel Creek is greater than 5 and 9% to 12% of the time it is less than 5. The lowest pH is predicted for when both Cannel Creek and the AMD are at high flow conditions (“c” category). During this stage, the pH is predicted to be between 4.19 and 4.28.

The effects of a typical storm event in the area lasts for approximately three days, from start of precipitation to end of precipitation and return of flow rates to near base level conditions. The duration of each of the five flow condition categories during a typical three-day storm event is also shown in the tables. Once treatment of the Bellvue AMD commences, the

category with the lowest resulting pH in Cannel Creek ("c" category) is predicted to last for approximately 13 hours during each storm event and is expected to occur 9% of the time.

Table 3. Modelling results for Cannel Creek below Bellvue AMD assuming 1 L/s treatment of Bellvue AMD.

Frequency	Duration in three-day storm	Condition	Cannel Creek flow (L/s)		Bellvue AMD flow (L/s)		Cannel Creek (just above and just below Bellvue Mine)

James Mine AMD and Cannel Creek

Modelling predicts the current pH in Cannel Creek downstream of the James Mine AMD ranges between 2.87 and 4.25, depending on relative flow rates of the stream and the AMD and depending on if Fe and Al minerals are at equilibrium with the water (Table 4).

Table 4. Modelling results for Cannel Creek below James Mine AMD under current conditions.

Frequency	Duration in three-day storm	Condition	Cannel Creek flow upstream of James Mine		James Mine AMD flow (L/s)		Cannel Creek (just above and just below James Mine)							
							pH		Fe		Al		Alkalinity	
							Upstream	Downstream	Upstream	Downstream	Upstream	Downstream	Upstream	Downstream

								2.87		9.47		19.5		

When comparing precipitation categories, the pattern of the severity of impact on pH to Cannel Creek is identical to that from the Bellvue Mine AMD. The lowest pH and highest metal concentrations occur at the very end of precipitation events.

Once treatment of up to 1 L/s of the Bellvue AMD begins, the results show that overall, 49% of the time the pH in Cannel Creek downstream of the James Mine AMD is greater than 5, 29% of the time the pH is between 4 and 5, and 22% of the time the pH is between 3 and 4 (Table 5). The lowest pH is predicted for the "e" category. During this stage, 1 L/s of Bellvue AMD is being treated but 0.5 L/s is not being treated and 0.25 L/s of James Mine AMD is discharging to Cannel Creek and the resulting pH is between 3.30 and 3.47. During a typical storm event, this category is predicted to last for approximately four hours and is expected to occur only 3% of the time.

James Creek and Cannel Creek

Modelling predicts the current pH in Cannel Creek downstream of James Creek ranges between 2.98 and 6.49, depending on relative flow rates of the two streams and the two AMDs and depending on if Fe and Al minerals are at equilibrium with the water (Table 6).

Table 5. Modelling results for Cannel Creek below James Mine assuming 1 L/s treatment of Bellvue AMD.

Frequency	Duration in three-day storm	Condition	Cannel Creek flow upstream of James Mine		James Mine AMD flow (L/s)		Cannel Creek (just above and just below James Mine)							
							pH		Fe		Al		Alkalinity	
							Upstream	Downstream	Upstream	Downstream	Upstream	Downstream	Upstream	Downstream

								3.74		0.15		3.19		0
10%	*14 hours*	end precipitation-1	moderate flow	26.5	moderate flow	0.25	5.25	3.98	0.24	1.50	0.43	2.02	8.38	0
								3.89		0.10		2.02		0
3%	*4 hours*	end precipitation-2	base flow	5	moderate flow	0.25	5.63	3.47	0.22	7.43	1.53	10.1	8.02	0
								3.30		0.98		10.1		0

When comparing precipitation categories, the pattern of the severity of impact on pH to Cannel Creek is identical to that from the Bellvue Mine AMD and James Mine AMD. The lowest pH and highest metal concentrations occur at the very end of precipitation events.

Once treatment of up to 1 L/s of the Bellvue AMD begins, the results show that overall, 78% of the time the pH in Cannel Creek downstream of the tributary is greater than 6, 19% of the time the pH is between 4 and 6 (as high as 5.29), and 3% of the time the pH is between 3 and 4 (Table 7). The lowest pH is predicted for the "e" category, when Cannel Creek and James Creek have returned to near base-flow flow rates and both the Bellvue Mine AMD and James Mine AMD are still flowing at moderate flow rates.

Table 6. Modelling results for Cannel Creek below James Creek under current conditions.

Frequency	Duration in three-day storm	Condition	Cannel Creek flow downstream of		James Creek flow (L/s)		Cannel Creek (just above and just below James Creek)							
							pH		Fe		Al		Alkalinity	
							Upstream	Downstream	Upstream	Downstream	Upstream	Downstream	Upstream	Downstream

Discussion

This work shows that the greatest impact to Cannel Creek from the Bellvue Mine AMD and the James Mine AMD occur at the tail end of storm events, when the flow rates in Cannel Creek have returned to near base level but the flow rates in the AMD are still elevated due to the lag in response time to precipitation. This situation may be common for abandoned

underground mines that are near the surface and affected by rainfall (through fracturing, etc.), which discharge AMD to surface water streams and may even occur with large overburden dumps. Dilution of the acidity from the AMD by Cannel Creek occurs to some extent during high flow events, however, this is tempered by the increased acid load in the AMD with increased flow.

Once the Bellvue AMD is being treated, the flow conditions which will have the greatest impact on Cannel Creek will no longer be at the tail end of storm events, but rather, will be during the highest flow events, when a relatively smaller proportion of the AMD is being treated and stream dilution is not adequate. Downstream however, the greatest impact to Cannel Creek from the James Mine AMD will continue to be during the post-storm event periods, even under the Bellvue AMD treatment scenario. This is because no treatment will be undertaken at the James Mine and the post-storm event scenario involves the least dilution effects of the AMD by Cannel Creek. Likewise, recovery of Cannel Creek after the junction with James Creek will be least during these post-storm events. Fortunately, these post-storm event periods only occur three percent of the time and last for approximately four hours each time.

Ideally, pH levels above 4.5 and metal concentrations below 1 mg/L are necessary for the ecology in the stream to recover. For approximately 49% of the time this condition will be met for the entire Cannel Creek from Bellvue Mine to the junction with the Nine Mile Creek (1.6 km). For the other 51% of the time, the section from James Mine to James Creek (150 m) will not meet this condition. For approximately 9% of the time the section between Bellvue Mine and the James Mine (550 m) will also not meet this condition, and for approximately 3% of the time the section from James Creek to the Nine Mile Creek (890 m) will not meet this condition. It is possible that once the ecology has recovered adequately, it can withstand these short duration pulses of acidic water during precipitation events.

The results of this analysis suggest that contingencies for treatment during Bellvue Mine AMD high flow events should be considered to avoid any pH drop in the stream during these events. Likewise, if additional alkalinity can be added to Cannel Creek during post-storm event periods, there would be less of a drop in pH downstream of the James Mine AMD.

Conclusion

The abandoned Bellvue Mine and James Mine both discharge AMD to nearby Cannel Creek. The Bellvue AMD has a pH between 2.28 and 3.01 and contains elevated concentrations of dissolved metals (69 mg/L Fe, 39 mg/L Al, 0.76 mg/L Mn, 0.32 mg/L Zn, 0.15 mg/L Ni). The James Mine AMD has a much lower flow rate than the Bellvue Mine AMD and has a pH of 2.41-2.80 and metal concentrations of 148 mg/L Fe, 200 mg/L Al, 6.5 mg/L Mn, 1.21 mg/L Zn and 0.56 mg/L Ni. Between 60% and 90% of the hydrogen ion acidity contribution from these two sources is from the Bellvue Mine AMD. The water quality in Cannel Creek degrades from near-neutral pH with low metal concentrations to an acidic stream with high metal concentrations. Both AMD sites show a delayed response to precipitation events, resulting in an asynchronous flow rate pattern with Cannel Creek. The greatest impact to Cannel Creek occurs during post-storm event periods, when the AMD flow rates are still elevated but Cannel Creek is returning to base level.

Once planned treatment is installed at the Bellvue Mine, it is expected that the entire length of Cannel Creek from Bellvue to the Nine Mine Creek (1.6 km) will be restored to a pH above 5

during low-flow conditions between precipitation events (49% of the time), which should allow the aquatic ecosystem to recover. However, during precipitation events, various sections of Cannel Creek may not meet a minimum recommended pH of 4.5 for a healthy ecosystem. For 9% of the time, the section from the Bellvue Mine to the James Creek tributary (700 m) may not meet this condition and for 3% of the time the section from James Creek to the Nine Mile Creek (890 m) may not meet this condition. During all stages of precipitation events (51% of the time), the short section between the James Mine and James Creek (150 m) is expected to have a pH below 4.5. It is possible, however, that once recovered, the aquatic ecosystem can withstand these short duration pulses of acidic water during precipitation events. As a result of this work, contingencies for treatment during high flow events will be considered.
